Package 'glmmPen'

April 22, 2022

```
Type Package
Title High Dimensional Penalized Generalized Linear Mixed Models
      (pGLMM)
Version 1.5.1.10
Date 2022-04-18
Maintainer Hillary Heiling <a href="https://www.unc.edu">heiling@live.unc.edu</a>
Description Fits high dimensional penalized generalized linear
      mixed models using
      the Monte Carlo Expectation Conditional Minimization (MCECM) algorithm.
      The purpose of the package is to perform variable selection on both the fixed and
      random effects simultaneously for generalized linear mixed models.
      The package supports fitting of Binomial, Gaussian, and Poisson data with canonical links, and
      supports penalization using the MCP, SCAD, or LASSO penalties. The MCECM algorithm
      is described in Rashid et al. (2020) <doi:10.1080/01621459.2019.1671197>.
      The techniques used in the minimization portion of the procedure (the M-step) are
      derived from the procedures of the 'ncvreg' package (Breheny and Huang (2011)
      <a href="https://doi:10.1214/10-AOAS388">> and 'grpreg' package (Breheny and Huang (2015))</a>
      <doi:10.1007/s11222-013-9424-2>), with
      appropriate modifications to account for the estimation and penalization of
      the random effects. The 'ncvreg' and 'grpreg' packages also describe the MCP, SCAD,
      and LASSO penalties.

Description

Control of Metropolis-within-Gibbs Adaptive Random Walk Sampling Procedure Controls the adaptive random walk Metropolis-within-Gibbs sampling procedure.

Gibbs sampling procedure.

basal 3

Usage

```
adaptControl(batch_length = 100, offset = 0)
```

Arguments

batch_length positive integer specifying the number of posterior samples to collect before the

proposal variance is adjusted based on the acceptance rate of the last batch_length accepted posterior samples. Default is set to 100. Batch length restricted to be

no less than 50.

offset non-negative integer specifying an offset value for the increment of the proposal

variance adjustment. Optionally used to ensure the required diminishing adap-

tation condition. Default set to 0.

increment = min(0.01, 1 / sqrt(batch*batch_length + offset))

Value

Function returns a list (inheriting from class "adaptControl") containing parameter specifications for the adaptive random walk sampling procedure.

basal

Basal dataset: A composition of cancer datasets with top scoring pairs (TSPs) as covariates and binary response indicating if the subject's cancer subtype was basal-like. A dataset composed of four datasets combined from studies that contain gene expression data from subjects with several types of cancer. Two of these datasets contain gene expression data for subjects with Pancreatic Ductal Adenocarcinoma (PDAC), one dataset contains data for subjects with Breast Cancer, and the fourth dataset contains data for subjects with Bladder Cancer. The response of interest is whether or not the subject's cancer subtype was the basal-like subtype. See articles Rashid et al. (2020) "Modeling Between-Study Heterogeneity for Improved Replicability in Gene Signature Selection and Clinical Prediction" and Moffitt et al. (2015) "Virtual microdissection identifies distinct tumor- and stroma-specific subtypes of pancreatic ductal adenocarcinoma" for further details on these four datasets.

Description

Basal dataset: A composition of cancer datasets with top scoring pairs (TSPs) as covariates and binary response indicating if the subject's cancer subtype was basal-like.

A dataset composed of four datasets combined from studies that contain gene expression data from subjects with several types of cancer. Two of these datasets contain gene expression data for subjects with Pancreatic Ductal Adenocarcinoma (PDAC), one dataset contains data for subjects with Breast Cancer, and the fourth dataset contains data for subjects with Bladder Cancer. The response of interest is whether or not the subject's cancer subtype was the basal-like subtype. See articles Rashid et al. (2020) "Modeling Between-Study Heterogeneity for Improved Replicability in Gene Signature Selection and Clinical Prediction" and Moffitt et al. (2015) "Virtual microdissection identifies distinct tumor- and stroma-specific subtypes of pancreatic ductal adenocarcinoma" for further details on these four datasets.

Usage

```
data("basal")
```

Format

A list containing the following elements:

- y binary response vector; 1 indicates that the subject's cancer was of the basal-like subtype, 0 otherwise
- **X** matrix of 50 top scoring pair (TSP) covariates
- **group** factor indicating which cancer study the observation belongs to, which are given the following descriptions: UNC PDAC, TCGA PDAC, TCGA Bladder Cancer, and UNC Breast Cancer
- **Z** model matrix for random effects; organized first by variable, then by group (groups {1,2,3,4} correspond to studies UNC_PDAC, TCGA_PDAC, TCGA_Bladder, and UNC_Breast)

fit_dat

Fit a Penalized Generalized Mixed Model via Monte Carlo Expectation Conditional Minimization (MCECM) fit_dat is used to fit a penalized generalized mixed model via Monte Carlo Expectation Conditional Minimization (MCECM) for a single tuning parameter combinations and is called within glmmPen or glmm (cannot be called directly by user)

Description

Fit a Penalized Generalized Mixed Model via Monte Carlo Expectation Conditional Minimization (MCECM)

fit_dat is used to fit a penalized generalized mixed model via Monte Carlo Expectation Conditional Minimization (MCECM) for a single tuning parameter combinations and is called within glmmPen or glmm (cannot be called directly by user)

Usage

```
fit_dat(
  dat,
  lambda0 = 0,
 lambda1 = 0,
  conv_EM = 0.001,
  conv_CD = 1e-04,
  family = "binomial",
 offset_fit = NULL,
  trace = 0,
 penalty = c("MCP", "SCAD", "lasso"),
 alpha = 1,
  gamma_penalty = switch(penalty[1], SCAD = 4, 3),
  group_X = 0:(ncol(dat$X) - 1),
 nMC_burnin = 250,
 nMC = 250,
  nMC_max = 5000,
```

```
t = 2,
mcc = 2.
u_init = NULL,
coef_old = NULL,
ufull_describe = NULL,
maxitEM = 50,
maxit_CD = 250,
M = 10^4,
sampler = c("stan", "random_walk", "independence"),
adapt_RW_options = adaptControl(),
covar = c("unstructured", "independent"),
var_start = 1,
logLik_calc = FALSE,
checks_complete = FALSE,
ranef_keep = rep(1, times = (ncol(dat$Z)/nlevels(dat$group))),
conv_type = 1,
progress = TRUE
```

Arguments

dat a list object specifying y (response vector), X (model matrix of all covariates), Z

(model matrix for the random effects), and group (numeric factor vector whose value indicates the study, batch, or other group identity to which on observation

belongs)

lambda0 a non-negative numeric penalty parameter for the fixed effects coefficients

lambda1 a non-negative numeric penalty parameter for the (grouped) random effects co-

variance coefficients

conv_EM a non-negative numeric convergence criteria for the convergence of the EM al-

gorithm. Default is 0.0015. EM algorithm is considered to have converge if the average Euclidean distance between the current coefficient estimates and the coefficient estimates from t EM iterations back is less than conv_EM mcc times

in a row. See t and mcc for more details.

conv_CD a non-negative numeric convergence criteria for the convergence of the grouped

coordinate descent loop within the M step of the EM algorithm. Default 0.0005.

family a description of the error distribution and link function to be used in the model. Currently, the glmmPen algorithm allows the Binomial, Gaussian, and Poisson

families with canonical links only.

offset_fit This can be used to specify an a priori known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length

equal to the number of cases.

equal to the number of cases.

trace an integer specifying print output to include as function runs. Default value is 0.

See Details for more information about output provided when trace = 0, 1, or 2.

penalty character describing the type of penalty to use in the variable selection proce-

dure. Options include 'MCP', 'SCAD', and 'lasso'. Default is MCP penalty. If the random effect covariance matrix is "unstructured", then a group MCP, group SCAD, or group LASSO penalty is used on the random effects coefficients. See Breheny and Huang (2011) <doi:10.1214/10-AOAS388> and Breheny and Huang (2015) <doi:10.1007/s11222-013-9424-2> for details of these penalties.

alpha Tuning parameter for the Mnet estimator which controls the relative contri-

butions from the MCP/SCAD/LASSO penalty and the ridge, or L2, penalty. alpha=1 is equivalent to the MCP/SCAD/LASSO penalty, while alpha=0 is equivalent to ridge regression. However, alpha=0 is not supported; alpha may

be arbitrarily small, but not exactly zero

gamma_penalty The scaling factor of the MCP and SCAD penalties. Not used by LASSO

penalty. Default is 4.0 for SCAD and 3.0 for MCP. See Breheny and Huang

(2011) < doi: 10.1214/10-AOAS388 > and Breheny and Huang (2015) < doi: 10.1007/s11222-10.1007/s1122-10.1007/s1122-10.1007/s11007/s112-10.1007/s112-10.1007

013-9424-2> for further details.

group_X vector describing the grouping of the covariates in the model matrix.

nMC_burnin positive integer specifying the number of posterior samples to use as burn-in for

each E step in the EM algorithm. If set to NULL, the algorithm inputs the following defaults: Default 250 when the number of random effects predictors is less than or equal to 10; default 100 otherwise. Function will not allow nMC_burnin

to be less than 100.

nMC a positive integer for the initial number of Monte Carlo draws. See the nMC_start

argument in optimControl for more details.

nMC_max a positive integer for the maximum number of allowed Monte Carlo draws used

in each step of the EM algorithm. If set to NULL, the algorithm inputs the following defaults: When the number of random effect covariates is greater than 10, the default is set to 1000; when the number of random effect covariates is 10

or less, the default is set to 2500.

t the convergence criteria is based on the average Euclidean distance between

the most recent coefficient estimates and the coefficient estimates from t EM

iterations back. Positive integer, default equals 2.

mcc the number of times the convergence criteria must be met before the algorithm

is seen as having converged (mcc for 'meet condition counter'). Default set to

2. Value restricted to be no less than 2.

u_init matrix giving values to initialize samples from the posterior. If Binomial or

Poisson families, only need a single row to initialize samples from the posterior; if Gaussian family, multiple rows needed to initialize the estimate of the residual error (needed for the E-step). Columns correspond to the columns of the Z

random effect model matrix.

coef_old vector giving values to initialized the coefficients (both fixed and random effects)

ufull_describe output from bigmemory::describe (which returns a list of the information

needed to attach to a big.matrix object) applied to the big.matrix of posterior samples from the 'full' model. The big.matrix described by the object is used to

calculate the BIC-ICQ value for the model.

maxitEM a positive integer for the maximum number of allowed EM iterations. If set to

NULL, then the algorithm inputs the following defaults: Default equals 50 for the

Binomial and Poisson families, 65 for the Gaussian family.

maxit_CD a positive integer for the maximum number of allowed iterations for the coor-

dinate descent algorithms used within the M-step of each EM iteration. Default

equals 50.

M positive integer specifying the number of posterior samples to use within the

Pajor log-likelihood calculation. Default is 10⁴; minimum allowed value is

5000.

sampler

character string specifying whether the posterior samples of the random effects should be drawn using Stan (default, from package rstan) or the Metropolis-within-Gibbs procedure incorporating an adaptive random walk sampler ("random_walk") or an independence sampler ("independence"). If using the random walk sampler, see adaptControl for some additional control structure parameters.

adapt_RW_options

a list of class "adaptControl" from function adaptControl containing the control parameters for the adaptive random walk Metropolis-within-Gibbs procedure. Ignored if optimControl parameter sampler is set to "stan" (default) or "independence".

covar

character string specifying whether the covariance matrix should be unstructured ("unstructured") or diagonal with no covariances between variables ("independent"). Default is set to NULL. If covar is set to NULL and the number of random effects predictors (not including the intercept) is greater than or equal to 10 (i.e. high dimensional), then the algorithm automatically assumes an independent covariance structure and covar is set to "independent". Otherwise if covar is set to NULL and the number of random effects predictors is less than 10, then the algorithm automatically assumes an unstructured covariance structure and covar is set to "unstructured".

var_start

either the character string "recommend" or a positive number specifying the starting values to initialize the variance of the covariance matrix. Default "recommend" first fits a simple model with a fixed and random intercept only using the lme4 package. The random intercept variance estimate from this model is then multiplied by 2 and used as the starting variance.

logLik_calc

logical value specifying if the log likelihood (and log-likelihood based calculations BIC, BICh, and BICNgrp) should be calculated for all of the models in the selection procedure. If BIC-ICQ is used for selection, the log-likelihood is not needed for each model. However, if users are interested in comparing the best models from BIC-ICQ and other BIC-type selection criteria, setting logLik_calc to TRUE will calculate these other quantities for all of the models.

checks_complete

logical value indicating whether the function has been called within glmm or glmmPen or whether the function has been called by itself. Used for package testing purposes (user cannot directly call fit_dat). If true, performs additional checks on the input data. If false, assumes data input checks have already been performed.

ranef_keep

vector of 0s and 1s indicating which random effects should be considered as non-zero at the start of the algorithm. For each random effect, 1 indicates the random effect should be considered non-zero at start of algorithm, 0 indicates otherwise. The first element for the random intercept should always be 1.

conv_type

integer specifying which type of convergence criteria to use. Default 1 specifies using the average Eucledian distance, and 2 specifies using relative change in the Q-function estimate. For now, all calls to fit_dat within the glmmPen framework restrict this convergence type to be the average Euclidean distance. However, we keep this argument in case we decide to allow multiple convergence type options in future versions of the package.

progress

a logical value indicating if additional output should be given showing the progress of the fit procedure. If TRUE, such output includes iteration-level information for the fit procedure (iteration number EM_iter, number of MCMC samples nMC, average Euclidean distance between current coefficients and coefficients from

8 glFormula_edit

t—defined in optimControl—iterations back EM_conv, and number of non-zero fixed and random effects covariates not including the intercept). Additionally, progress = TRUE gives some other information regarding the progress of the variable selection procedure, including the model selection criteria and log-likelihood estimates for each model fit. Default is TRUE.

Value

a list with the following elements:

coef a numeric vector of coefficients of fixed effects estimates and non-zero estimates

of the lower-triangular cholesky decomposition of the random effects covariance

matrix (in vector form)

sigma random effects covariance matrix

lambda0, lambda1

the penalty parameters input into the function

covgroup Organization of how random effects coefficients are grouped.

J a sparse matrix that transforms the non-zero elements of the lower-triangular

cholesky decomposition of the random effects covariance matrix into a vector. For unstructured covariance matrices, dimension of dimension $q^2 x (q(q+1)/2)$ (where q = number of random effects). For independent covariance matrices,

q^2 x q.

11 estimate of the log likelihood, calculated using the Pajor method

BICh the hybrid BIC estimate described in Delattre, Lavielle, and Poursat (2014)

BIC Regular BIC estimate

BICNgrps BIC estimate with N = number of groups in penalty term instead of N = number

of total observations.

BIC-ICQ estimate

u a matrix of the Monte Carlo draws. Organization of columns: first by ran-

dom effect variable, then by group within variable (i.e. Var1:Grp1 Var1:Grp2 ...

Var1:GrpK Var2:Grp1 ... Varq:GrpK)

gibbs_accept_rate

a matrix of the ending gibbs acceptance rates for each variable (columns) and each group (rows) when the sampler is either "random_walk" or "independence"

proposal_SD

a matrix of the ending proposal standard deviations (used in the adaptive ran-

dom walk version of the Metropolis-within-Gibbs sampling) for each variable

(columns) and each group (rows)

glFormula_edit

Extracting Useful Vectors and Matrices from Formula and Data Information

Description

Takes the model formula and an optional data frame and converts them into y, X, Z, and group output.

glFormula_edit 9

Usage

```
glFormula_edit(
  formula,
  data = NULL,
  family,
  subset,
  weights,
  na.action,
  offset,
  ...
)
```

Arguments

formula a two-sided linear formula object describing both the fixed-effects and random-

effects part of the model, with the response on the left of a ~ operator and the terms, sepearated by + operators, on the right. Random-effects terms are distinguished by vertical bars ("I") separating expression for design matrices from grouping factors. formula should be of the same format needed for glmer in package lme4. Only one grouping factor will be recognized. The random effects covariates need to be a subset of the fixed effects covariates. The offset must be

specified outside of the formula in the 'offset' argument.

data an optional data frame containing the variables named in formula. Although

data is optional, the package authors *strongly* recommend its use. If data is omitted, variables will be taken from the environment of formula (if specified

as a formula).

family a description of the error distribution and link function to be used in the model

(a family function or the result of a call to a family function). (See family for

details of family functions.)

subset an optional vector specifying a subset of observations to be used in the fitting

process.

weights an optional vector of 'prior weights' to be used in the fitting process. Should be

NULL or a numeric vector.

na.action a function that indicates what should happen when the data contain NAs. The

default option na.omit removes observations with any missing values in any of

the variables

offset this can be used to specify an a priori known component to be included in the

linear predictor during fitting. This should be NULL or a numeric vector of

length equal to the number of cases.

... potential further arguments

Value

a list with the following elements:

fr a model frame including all fixed and random covariates, the response, and the

grouping variable

X fixed effects covariates model matrix

reTrms list containing several items relating to the random effects

family specified for data modeling

10 glmm

formula formula

fixed_vars vector of variable names used for fixed effects fwmsgs indicator for a check of the group levels

glmm

Fit a Generalized Mixed Model via Monte Carlo Expectation Conditional Minimization (MCECM)

Description

glmm is used to fit a single generalized mixed model via Monte Carlo Expectation Conditional Minimization (MCECM). Unlike glmmPen, no model selection is performed.

Usage

```
glmm(
  formula,
  data = NULL,
  family = "binomial",
  covar = NULL,
  offset = NULL,
  optim_options = optimControl(),
  adapt_RW_options = adaptControl(),
  trace = 0,
  tuning_options = lambdaControl(),
  progress = TRUE,
  ...
)
```

Arguments

formula

a two-sided linear formula object describing both the fixed effects and random effects part of the model, with the response on the left of a ~ operator and the terms, separated by + operators, on the right. Random-effects terms are distinguished by vertical bars ("I") separating expression for design matrices from the grouping factor. formula should be of the same format needed for glmer in package lme4. Only one grouping factor will be recognized. The random effects covariates need to be a subset of the fixed effects covariates. The offset must be specified outside of the formula in the 'offset' argument.

data

an optional data frame containing the variables named in formula. If data is omitted, variables will be taken from the environment of formula.

family

a description of the error distribution and link function to be used in the model. Currently, the glmmPen algorithm allows the Binomial, Gaussian, and Poisson families with canonical links only.

covar

character string specifying whether the covariance matrix should be unstructured ("unstructured") or diagonal with no covariances between variables ("independent"). Default is set to NULL. If covar is set to NULL and the number of random effects predictors (not including the intercept) is greater than or equal to 10 (i.e. high dimensional), then the algorithm automatically assumes an independent covariance structure and covar is set to "independent". Otherwise if covar is

glmm 11

set to NULL and the number of random effects predictors is less than 10, then the algorithm automatically assumes an unstructured covariance structure and covar is set to "unstructured".

offset

This can be used to specify an *a priori* known component to be included in the linear predictor during fitting. Default set to NULL (no offset). If the data argument is not NULL, this should be a numeric vector of length equal to the number of cases (the length of the response vector). If the data argument specifies a data.frame, the offset argument should specify the name of a column in the data.frame.

optim_options

a structure of class "optimControl" created from function optimControl that specifies several optimization parameters. See the documentation for optimControl for more details on defaults.

adapt_RW_options

a list of class "adaptControl" from function adaptControl containing the control parameters for the adaptive random walk Metropolis-within-Gibbs procedure. Ignored if optimControl parameter sampler is set to "stan" (default) or "independence".

trace

an integer specifying print output to include as function runs. Default value is 0. See Details for more information about output provided when trace = 0, 1, or 2.

tuning_options

a list of class "selectControl" or "lambdaControl" resulting from selectControl or lambdaControl containing additional control parameters. When function glmm is used,the algorithm may be run using one specific set of penalty parameters lambda0 and lambda1 by specifying such values in lambdaControl(). The default for glmm is to run the model fit with no penalization (lambda0 = lambda1 = 0). When function glmmPen is run, tuning_options is specified using selectControl(). See the lambdaControl and selectControl documentation for further details.

progress

a logical value indicating if additional output should be given showing the progress of the fit procedure. If TRUE, such output includes iteration-level information for the fit procedure (iteration number EM_iter, number of MCMC samples nMC, average Euclidean distance between current coefficients and coefficients from t—defined in optimControl—iterations back EM_conv, and number of non-zero fixed and random effects covariates not including the intercept). Additionally, progress = TRUE gives some other information regarding the progress of the variable selection procedure, including the model selection criteria and log-likelihood estimates for each model fit. Default is TRUE.

additional arguments that could be passed into glmmPen. See glmmPen for further details.

Details

The glmm function can be used to fit a single generalized mixed model. While this approach is meant to be used in the case where the user knows which covariates belong in the fixed and random effects and no penalization is required, one is allowed to specify non-zero fixed and random effects penalties using lambdaControl and the (...) arguments. The (...) allow for specification of penalty-related arguments; see glmmPen for details. For a high dimensional situation, the user may want to fit a minimal penalty model using a small penalty for the fixed and random effects and save the posterior samples from this minimal penalty model for use in any BIC-ICQ calculations during selection within glmmPen. Specifying a file name in the 'BICq_posterior' argument will save the posterior samples from the glmm model into a big.matrix with this file name, see the Details section of glmmPen for additional details.

12 glmmPen

Value

A reference class object of class pglmmObj for which many methods are available (e.g. methods(class = "pglmmObj"))

glmmPen

Fit Penalized Generalized Mixed Models via Monte Carlo Expectation Conditional Minimization (MCECM)

Description

glmmPen is used to fit penalized generalized mixed models via Monte Carlo Expectation Conditional Minimization (MCECM). The purpose of the function is to perform variable selection on both the fixed and random effects simultaneously for the generalized linear mixed model. glmmPen selects the best model using BIC-type selection criteria (see selectControl documentation for further details)

Usage

```
glmmPen(
  formula,
  data = NULL,
  family = "binomial",
  covar = NULL,
 offset = NULL,
  fixef_noPen = NULL,
  penalty = c("MCP", "SCAD", "lasso"),
  alpha = 1,
  gamma_penalty = switch(penalty[1], SCAD = 4, 3),
  optim_options = optimControl(),
  adapt_RW_options = adaptControl(),
  trace = 0,
  tuning_options = selectControl(),
 BICq_posterior = NULL,
 progress = TRUE
)
```

Arguments

formula

a two-sided linear formula object describing both the fixed effects and random effects part of the model, with the response on the left of a ~ operator and the terms, separated by + operators, on the right. Random-effects terms are distinguished by vertical bars ("I") separating expression for design matrices from the grouping factor. formula should be of the same format needed for glmer in package lme4. Only one grouping factor will be recognized. The random effects covariates need to be a subset of the fixed effects covariates. The offset must be specified outside of the formula in the 'offset' argument.

data

an optional data frame containing the variables named in formula. If data is omitted, variables will be taken from the environment of formula.

family

a description of the error distribution and link function to be used in the model. Currently, the glmmPen algorithm allows the Binomial, Gaussian, and Poisson families with canonical links only.

glmmPen 13

covar

character string specifying whether the covariance matrix should be unstructured ("unstructured") or diagonal with no covariances between variables ("independent"). Default is set to NULL. If covar is set to NULL and the number of random effects predictors (not including the intercept) is greater than or equal to 10 (i.e. high dimensional), then the algorithm automatically assumes an independent covariance structure and covar is set to "independent". Otherwise if covar is set to NULL and the number of random effects predictors is less than 10, then the algorithm automatically assumes an unstructured covariance structure and covar is set to "unstructured".

offset

This can be used to specify an a priori known component to be included in the linear predictor during fitting. Default set to NULL (no offset). If the data argument is not NULL, this should be a numeric vector of length equal to the number of cases (the length of the response vector). If the data argument specifies a data.frame, the offset argument should specify the name of a column in the data.frame.

fixef_noPen

Optional vector of 0's and 1's of the same length as the number of fixed effects covariates used in the model. Value 0 indicates the variable should not have its fixed effect coefficient penalized, 1 indicates that it can be penalized. Order should correspond to the same order of the fixed effects given in the formula.

penalty

character describing the type of penalty to use in the variable selection procedure. Options include 'MCP', 'SCAD', and 'lasso'. Default is MCP penalty. If the random effect covariance matrix is "unstructured", then a group MCP, group SCAD, or group LASSO penalty is used on the random effects coefficients. See Breheny and Huang (2011) <doi:10.1214/10-AOAS388> and Breheny and Huang (2015) <doi:10.1007/s11222-013-9424-2> for details of these penalties.

alpha

Tuning parameter for the Mnet estimator which controls the relative contributions from the MCP/SCAD/LASSO penalty and the ridge, or L2, penalty. alpha=1 is equivalent to the MCP/SCAD/LASSO penalty, while alpha=0 is equivalent to ridge regression. However, alpha=0 is not supported; alpha may be arbitrarily small, but not exactly zero

gamma_penalty

The scaling factor of the MCP and SCAD penalties. Not used by LASSO penalty. Default is 4.0 for SCAD and 3.0 for MCP. See Breheny and Huang (2011) <doi:10.1214/10-AOAS388> and Breheny and Huang (2015) <doi:10.1007/s11222-013-9424-2> for further details.

optim_options

a structure of class "optimControl" created from function optimControl that specifies several optimization parameters. See the documentation for optimControl for more details on defaults.

adapt_RW_options

a list of class "adaptControl" from function adaptControl containing the control parameters for the adaptive random walk Metropolis-within-Gibbs procedure. Ignored if optimControl parameter sampler is set to "stan" (default) or "independence".

trace

an integer specifying print output to include as function runs. Default value is 0. See Details for more information about output provided when trace = 0, 1, or 2.

tuning_options a list of class "selectControl" or "lambdaControl" resulting from selectControl or lambdaControl containing additional control parameters. When function glmm is used, the algorithm may be run using one specific set of penalty parameters lambda0 and lambda1 by specifying such values in lambdaControl(). The default for glmm is to run the model fit with no penalization (lambda θ = lambda1 = 0). When function glmmPen is run, tuning_options is specified 14 glmmPen

using selectControl(). See the lambdaControl and selectControl documentation for further details.

BICq_posterior

an optional character string expressing the path and file basename of a file combination that will file-back or currently file-backs a big.matrix of the posterior samples from the minimal penalty model used for the BIC-ICQ calculation used for model selection. T (BIC-ICQ reference: Ibrahim et al (2011) <doi:10.1111/j.1541-0420.2010.01463.x>). If this argument is specified as NULL (default) and BIC-ICQ calculations are requested (see selectControl) for details), the posterior samples will be saved in the file combination 'BICq_Posterior_Draws.bin' and 'BICq_Posterior_Draws.desc' in the working directory. See 'Details' section for additional details about the required format of BICq_posterior and the file-backed big matrix.

progress

a logical value indicating if additional output should be given showing the progress of the fit procedure. If TRUE, such output includes iteration-level information for the fit procedure (iteration number EM_iter, number of MCMC samples nMC, average Euclidean distance between current coefficients and coefficients from t-defined in optimControl-iterations back EM_conv, and number of non-zero fixed and random effects covariates not including the intercept). Additionally, progress = TRUE gives some other information regarding the progress of the variable selection procedure, including the model selection criteria and log-likelihood estimates for each model fit. Default is TRUE.

Details

Argument BICq_posterior details: If the BIC_option in selectControl (tuning_options) is specified to be 'BICq', this requests the calculation of the BIC-ICQ criterion during the selection process. For the BIC-ICQ criterion to be calculated, a minimal penalty model assuming a small valued lambda penalty needs to be fit, and the posterior samples from this minimal penalty model need to be used. In order to avoid repetitive calculations of this minimal penalty model (i.e. if secondary rounds of selection are desired in glmmPen_FineSearch or if the user wants to re-run glmmPen with a different set of penalty parameters), a big.matrix of these posterior samples will be file-backed as two files: a backing file with extension '.bin' and a descriptor file with extension '.desc'. The BICq_posterior argument should contain a path and a filename of the form "./path/filename" such that the backingfile and the descriptor file would then be saved as "./path/filename.bin" and "./path/filename.desc", respectively. If BICq_posterior is set to NULL, then by default, the backingfile and descriptor file are saved in the working directory as "BICq_Posterior_Draws.bin" and "BICq_Posterior_Draws.desc". If the big matrix of posterior samples is already file-backed, BICq_posterior should specify the path and basename of the appropriate files (again of form "./path/filename"); the minimal penalty model will not be fit again and the big.matrix of posterior samples will be read using the attach.big.matrix function of the bigmemory package and used in the BIC-ICQ calculations. If the appropriate files do not exist or BICq_posterior is specified as NULL, the minimal penalty model will be fit and the minimal penalty model posterior samples will be saved as specified above. The algorithm will save 10⁴ posterior samples automatically.

Trace details: The value of 0 (default) does not output any extra information. The value of 1 additionally outputs the updated coefficients, updated covariance matrix values, and the number of coordinate descent iterations used for the M step for each EM iteration. When pre-screening procedure is used and/or if the BIC-ICQ criterion is requested, trace = 1 gives additional information about the penalties used for the 'minimal penalty model' fit procedure. If Stan is not used as the E-step sampling mechanism, the value of 2 outputs all of the above plus gibbs acceptance rate information for the adaptive random walk and independence samplers and the updated proposal standard deviation for the adaptive random walk.

glmmPen_FineSearch 15

Value

A reference class object of class pglmmObj for which many methods are available (e.g. methods(class = "pglmmObj"), see ?pglmmObj for additional documentation)

glmmPen_FineSearch

Fit a Penalized Generalized Mixed Model via Monte Carlo Expectation Conditional Minimization (MCECM) using a finer penalty grid search glmmPen_FineSearch finds the best model from the selection results of a pglmmObj object created by glmmPen, identifies a more targeted grid search around the optimum lambda penalty values, and performs model selection on this finer grid search.

Description

Fit a Penalized Generalized Mixed Model via Monte Carlo Expectation Conditional Minimization (MCECM) using a finer penalty grid search

glmmPen_FineSearch finds the best model from the selection results of a pglmmObj object created by glmmPen, identifies a more targeted grid search around the optimum lambda penalty values, and performs model selection on this finer grid search.

Usage

```
glmmPen_FineSearch(
  object,
  tuning_options = selectControl(),
 BIC_option = NULL,
  idx_range = 2,
  optim_options = NULL,
  adapt_RW_options = NULL,
  trace = 0,
 BICq_posterior = NULL,
 progress = TRUE
)
```

Arguments

object

an object of class pglmmObj created by glmmPen. This object must contain model selection results.

tuning_options a list of class selectControl resulting from selectControl containing model selection control parameters. See the selectControl documentation for details. The user can specify their own fine grid search, or if the lambda0_seq and lambda1_seq arguments are left as NULL, the algorithm will automatically select a fine grid search based on the best model from the previous selection. See Details for more information. Default value set to 1.

BIC_option

character string specifying the selection criteria used to select the 'best' model. If left as the default NULL, then will use the same selection criteria used during the grid search used to produce the input pglmmObj object. See further details in the BIC_option description of selectControl.

idx_range

a positive integer that determines what positions within the sequence of the fixed and random effect lambda penalty parameters used in the previous coarse grid search will be used as the new fixed and random effect lambda penalty parameter ranges. See Details for more information.

optim_options

an optional list of class "optimControl" created from function optimControl that specifies optimization parameters. If set to the default NULL, will use the optimization parameters used for the previous round of selection stored within the pglmmObj object.

adapt_RW_options

an optional list of class "adaptControl" from function adaptControl containing the control parameters for the adaptive random walk Metropolis-within-Gibbs procedure. Ignored if optimControl parameter sampler is set to "stan" or "independence". If set to the default NULL, will use the adaptive random walk paraters used for the previous round of selection stored within the pglmmObj object.

trace

an integer specifying print output to include as function runs. Default value is 0. See Details of glmmPen for more information about output provided when trace = 0, 1, or 2.

BICq_posterior

an optional character string specifying the file-backed big.matrix containing the posterior draws used to calculate the BIC-ICQ selection criterion if such a big.matrix was created in the previous round of selection. See glmmPen documentation for further details.

progress

a logical value indicating if additional output should be given showing the progress of the fit procedure. If TRUE, such output includes iteration-level information for the fit procedure (iteration number EM_iter, number of MCMC draws nMC, average Euclidean distance between current coefficients and coefficients from t-defined in optimControl-iterations back EM_conv, and number of non-zero fixed and random effects including the intercept). Additionally, progress = TRUE gives some other information regarding the progress of the variable selection procedure, including the model selection criteria and log-likelihood estimates for each model fit. Default is TRUE.

Details

The glmmPen_FineSearch function extracts the data, the penalty information (penalty type, gamma_penalty, and alpha), the pre-screening results from the initial variable selection procedure, and some other argument specifications from the pglmmObj object created during a previous round of variable/model selection. In this finer grid search, the user has the ability to make the following adjustments: the user can change the BIC option used for selection, any optimization control parameters, or any adaptive random walk parameters (if the sampler specified in the optimization parameters is "random_walk"). The user could manually specify the lambda penalty grid to search over within the selectControl control parameters, or the user could let the glmmPen_FineSearch algorithm calculate a finer grid search automatically (see next paragraph for details).

If the sequences of lambda penalty values are left unspecified in the selectControl tuning options, the glmmPen_FineSearch algorithm performs the following steps to find the finer lambda grid search: (i) The lambda combination from the best model is identified from the earlier selection results saved in the pglmmObj object. (ii) For the fixed and random effects separately, the new max and min lambda values are the lambda values idx_range positions away from the best lambda in the original lambda sequences for the fixed and random effects. For instance, suppose we consider a hypothetical lambda sequence of {0.1,0.2,0.3,0.4,0.5,0.6,0.7} for both fixed and random effects, and the best model was given by the (0.4,0.5) combination. If the idx_lambda = 2, then the fine

lambdaControl 17

search would use the fixed effects sequence would have (min,max) = (0.2,0.6) and the fixed effects sequence would have (min,max) = (0.3,0.7).

Value

A reference class object of class pglmmObj for which many methods are available (e.g. methods(class = "pglmmObj"))

lambdaControl

Control of Penalization Parameters and Selection Criteria

Description

Constructs control structures for penalized mixed model fitting.

Usage

```
lambdaControl(lambda0 = 0, lambda1 = 0)

selectControl(
  lambda0_seq = NULL,
  lambda1_seq = NULL,
  nlambda = 10,
  search = c("abbrev", "full_grid"),
  BIC_option = c("BICq", "BICh", "BIC", "BICNgrp"),
  logLik_calc = switch(BIC_option[1], BICq = FALSE, TRUE),
  lambda.min = NULL,
  pre_screen = TRUE,
  lambda.min.presc = NULL
)
```

Arguments

lambda0 a non-negative numeric penalty parameter for the fixed effects coefficients

lambda1 a non-negative numeric penalty parameter for the (grouped) random effects co-

variance coefficients

lambda0_seq, lambda1_seq

a sequence of non-negative numeric penalty parameters for the fixed and random effect coefficients (lambda0_seq and lambda1_seq, respectively). If NULL, then a sequence will be automatically calculated. See 'Details' section for more

details on these default calculations.

nlambda

positive integer specifying number of penalty parameters to use for the fixed and random effects penalty parameters. Default set to 10. Only used if either lambda0_seq or lambda1_seq remain unspecified by the user (one or both of these arguments set to NULL) and, consequently, one or more default sequences

need to be calculated.

search

character string of "abbrev" (default) or "full_grid" indicating if the search of models over the penalty parameter space should be the full grid search (total number of models equals 'nlambda'^2 or length('lambda0_seq')*length('lambda1_seq'))

or an abbreviated grid search. The abbreviated grid search is described in more detail in the Details section. Te authors highly recommend the abbreviated grid

search.

18 lambdaControl

BIC_option

character string specifying the selection criteria used to select the 'best' model. Default "BICq" option specifies the BIC-ICQ criterion (Ibrahim et al (2011) <doi:10.1111/j.1541-0420.2010.01463.x>), which requires a fit of a 'minimum penalty' model; a small penalty (the minimum of the penalty sequence) is used for the fixed and random effects. See "Details" section for what these small penalties will be. The "BICh" option utilizes the hybrid BIC value described in Delattre, Lavielle, and Poursat (2014) <doi:10.1214/14-EJS890>. The regular "BIC" option penalty term uses (total non-zero coefficients)*(length(y) = total number observations). The "BICNgrp" option penalty term uses (total non-zero coefficients)*(nlevels(group) = number groups).

logLik_calc

logical value specifying if the log likelihood (and log-likelihood based calculations BIC, BICh, and BICNgrp) should be calculated for all of the models in the selection procedure. If BIC-ICQ is used for selection, the log-likelihood is not needed for each model. However, if users are interested in comparing the best models from BIC-ICQ and other BIC-type selection criteria, setting logLik_calc to TRUE will calculate these other quantities for all of the models.

lambda.min

numeric fraction between 0 and 1. The sequence of the lambda penalty parameters ranges from the maximum lambda where all fixed and random effects are penalized to 0 and a minimum lambda value, which equals a small fraction of the maximum lambda. The parameter lambda.min specifies this fraction. Default value is set to NULL, which automatically selects lambda.min to equal 0.01 when the number of observations is greater than the number of fixed effects predictors and 0.05 otherwise. Only used if either lambda0_seq or lambda1_seq remain unspecified by the user (one or both of these sequence arguments set to NULL) and, consequently, one or more default sequences need to be calculated.

pre_screen

logical value indicating whether pre-screening should be performed before model selection (default TRUE). If the number of random effects covariates considered is 4 or less, then no pre-screening will be performed. Pre-screening removes random effects from consideration during the model selection process, which can significantly speed up the algorithm. See "Details" section for a further discussion.

lambda.min.presc

numeric fraction between 0 and 1. During pre-screening and the minimal penalty model fit for the BIC-ICQ calculation, the small penalty used on the random effect is the fraction lambda.min.presc multiplied by the maximum penalty parameter that penalizes all fixed and random effects to 0. If left as NULL, the default value is 0.01 when the number of random effect covariates is 10 or less and 0.05 otherwise. Only used if lambda1_seq remains unspecified by the user (this argument set to NULL so the random effects penalty parameter sequence needs to be automatically calculated) AND either the pre-screening procedure is selected by the argument pre_screen or the BIC-ICQ is selected as the model selection criteria, i.e., BIC_option = "BICq". See the "Details" section for a further discussion.

Details

If left as the default NULL values, the lambda0_seq and lambda1_seq numeric sequences are automatically calculated. The sequence will be calculated in the same manner as nowneg calculates the range: the max value (let's denote this as lambda_max) penalizes all fixed and random effects to 0, the min value is a small portion of max (lambda.min*lambda_max), and the sequence is composed of nlambda values ranging from these min and max values spread evenly on the log scale. Unlike nowneg, the order of penalty values used in the algorithm must run from the min lambda to the max

lambdaControl 19

lambda (as opposed to running from max lambda to min lambda). The length of the sequence is specified by nlambda. By default, these sequences are calculated using LambdaSeq.

The lambda0 and lambda1 arguments used within the glmm function allow for a user to fit a model with a single non-zero penalty parameter combination. However, this is generally not recommended.

Abbreviated grid search: The abbreviated grid search proceeds in two stages. In stage 1, the algorithm fits the following series of models: the fixed effects penalty parameter remains a fixed value evaluated at the minimum of the fixed effects penalty parameters, and all random effects penalty parameters are examined. The 'best' model from this first stage of models determines the optimum random effect penalty parameter. In stage 2, the algorithm fits the following series of models: the random effects penalty parameter remains fixed at the value of the optimum random effect penalty parameter (from stage 1) and all fixed effects penalty parameters are considered. The best overall model is the best model from stage 2. This reduces the number of models considered to length('lambda0_seq') + length('lambda1_seq'). The authors found that this abbreviated grid search worked well in simulations, and performed considerably faster than the full grid search that examined all possible fixed and random effect penalty parameter combinations.

The arguments nlambda and lambda.min are only used if one or both of the lambda0_seq and lambda1_seq penalty sequences (corresponding to the fixed and random effects penalty sequences, respectively) remain unspecified by the user (one or both of these arguments left as NULL), indicating that the algorithm needs to calculate default penalty sequences.

The argument lambda.min.presc is only used under the following condition: lambda1_seq remains unspecified by the user (this argument set to NULL so the random effects penalty parameter sequence needs to be calculated) AND either the pre-screening procedure is selected by the argument pre_screen or the BIC-ICQ is selected as the model selection criteria, i.e., BIC_option = "BICq". If lambda1_seq is specified by the user, the minimum value in that sequence will be used as the random effect penalty in the pre-screening procedure and/or the minimal penalty model for the BIC-ICQ calculation.

BIC-ICQ calculation: This model selection criteria requires the fitting of a 'minimal penalty' model, which fits a model with a small penalty on the fixed and random effects. For the fixed effects penalty, the minimal penalty is: (a) 0 if the number of fixed effects covariates is 4 or less or (b) the minimum fixed effect penalty from the fixed effects penalty sequence (either from the default sequence or from the sequence specified by the user). For the random effects penalty, the minimal penalty is (a) 0 if the number of random effects covariates is 4 or less; (b) the minimum random effect penalty from the random effects penalty sequence specified by the user, or (c) lambda_min.presc multiplied to the lambda_max maximum penalty specified above when a default random effects penalty sequence is calculated.

Pre-screening: The minimum fixed effects penalty used in the pre-screening stage will be the minimum penalty of the fixed effects penalty sequence, lambda0_seq. The minimum random effects penalty used in the pre-screening stage will be either (a) the minimum random effects penalty in the sequence lambda1_seq if this sequence specified by the user, or (b) lambda.min.pres x lambda_max, where lambda_max was described above.

Value

The *Control functions return a list (inheriting from class "pglmmControl") containing parameter values that determine settings for variable selection.

20 LambdaSeq

LambdaSeq

Calculation of Penalty Parameter Sequence (Lambda Sequence)

Description

Calculates the sequence of penalty parameters used in the model selection procedure. This function calls functions from package novreg.

Usage

```
LambdaSeq(
   X,
   y,
   family,
   alpha = 1,
   lambda.min = NULL,
   nlambda = 10,
   penalty.factor = NULL)
```

Arguments

X matrix of standardized fixed effects (see std function in novreg documenation).

X should not include intercept.

y numeric vector of response values

family a description of the error distribution and link function to be used in the model.

Currently, the glmmPen algorithm allows the Binomial, Gaussian, and Poisson

families with canonical links only.

alpha Tuning parameter for the Mnet estimator which controls the relative contri-

butions from the MCP/SCAD/LASSO penalty and the ridge, or L2, penalty. alpha=1 is equivalent to the MCP/SCAD/LASSO penalty, while alpha=0 is equivalent to ridge regression. However, alpha=0 is not supported; alpha may

be arbitrarily small, but not exactly zero

lambda.min numeric fraction between 0 and 1. The sequence of the lambda penalty param-

eters ranges from the maximum lambda where all fixed and random effects are penalized to 0 and a minimum lambda value, which equals a small fraction of the maximum lambda. The parameter lambda.min specifies this fraction. Default value is set to NULL, which automatically selects lambda.min to equal 0.01 when the number of observations is greater than the number of fixed effects predictors and 0.05 otherwise. Only used if either lambda@_seq or lambdal_seq remain unspecified by the user (one or both of these sequence arguments set to NULL) and, consequently, one or more default sequences need to be calculated.

nlambda positive integer specifying number of penalty parameters (lambda) with which

to fit a model.

penalty.factor an optional numeric vector equal to the fixef_noPen argument in glmmPen

optimControl 21

Value

numeric sequence of penalty parameters of length nlambda ranging from the minimum penalty parameter (first element) equal to fraction lambda.min multiplied by the maximum penalty parameter to the maximum penalty parameter (last element)

optimControl

Control of Penalized Generalized Linear Mixed Model Fitting

Description

Constructs the control structure for the optimization of the penalized mixed model fit algorithm.

Usage

```
optimControl(
    conv_EM = 0.0015,
    conv_CD = 5e-04,
    nMC_burnin = NULL,
    nMC_start = NULL,
    nMC_max = NULL,
    nMC_report = 5000,
    maxitEM = NULL,
    maxit_CD = 50,
    M = 10000,
    t = 2,
    mcc = 2,
    sampler = c("stan", "random_walk", "independence"),
    var_start = "recommend"
)
```

Arguments

conv_EM

a non-negative numeric convergence criteria for the convergence of the EM algorithm. Default is 0.0015. EM algorithm is considered to have converge if the average Euclidean distance between the current coefficient estimates and the coefficient estimates from t EM iterations back is less than conv_EM mcc times in a row. See t and mcc for more details.

conv_CD

a non-negative numeric convergence criteria for the convergence of the grouped coordinate descent loop within the M step of the EM algorithm. Default 0.0005.

nMC_burnin

positive integer specifying the number of posterior samples to use as burn-in for each E step in the EM algorithm. If set to NULL, the algorithm inputs the following defaults: Default 250 when the number of random effects predictors is less than or equal to 10; default 100 otherwise. Function will not allow nMC_burnin to be less than 100.

nMC_start

a positive integer for the initial number of Monte Carlo draws. If set to NULL, the algorithm inputs the following defaults: Default 250 when the number of random effects predictors is less than or equal to 10; default 100 otherwise.

22 optimControl

nMC_max a positive integer for the maximum number of allowed Monte Carlo draws used in each step of the EM algorithm. If set to NULL, the algorithm inputs the following defaults: When the number of random effect covariates is greater than 10, the default is set to 1000; when the number of random effect covariates is 10 or less, the default is set to 2500. a positive integer for the number of posterior samples to save from the final nMC_report model. These posterior samples can be used for diagnostic purposes, see plot_mcmc. Default set to 5000. a positive integer for the maximum number of allowed EM iterations. If set to maxitEM NULL, then the algorithm inputs the following defaults: Default equals 50 for the Binomial and Poisson families, 65 for the Gaussian family. maxit_CD a positive integer for the maximum number of allowed iterations for the coordinate descent algorithms used within the M-step of each EM iteration. Default equals 50. Μ positive integer specifying the number of posterior samples to use within the Pajor log-likelihood calculation. Default is 10⁴; minimum allowed value is 5000. the convergence criteria is based on the average Euclidean distance between t the most recent coefficient estimates and the coefficient estimates from t EM iterations back. Positive integer, default equals 2. the number of times the convergence criteria must be met before the algorithm mcc is seen as having converged (mcc for 'meet condition counter'). Default set to 2. Value restricted to be no less than 2. sampler character string specifying whether the posterior samples of the random effects should be drawn using Stan (default, from package rstan) or the Metropoliswithin-Gibbs procedure incorporating an adaptive random walk sampler ("random_walk") or an independence sampler ("independence"). If using the random walk sampler, see adaptControl for some additional control structure parameters. either the character string "recommend" or a positive number specifying the var_start starting values to initialize the variance of the covariance matrix. Default "recommend" first fits a simple model with a fixed and random intercept only using the lme4 package. The random intercept variance estimate from this model is then multiplied by 2 and used as the starting variance.

Details

Several arguments are set to a default value of NULL. If these arguments are left as NULL by the user, then these values will be filled in with appropriate default values as specified above, which may depend on the number of random effects or the family of the data. If the user specifies particular values for these arguments, no additional modifications to these arguments will be done within the algorithm.

Value

Function returns a list inheriting from class optimControl containing fit and optimization criteria values used in optimization routine.

pglmmObj-class Class pglmmObj of Fitted Penalized Generalized Mixed-Effects Models for package glmmPen

Description

The functions glmm, glmmPen, and glmmPen_FineSearch from the package glmmPen output the reference class object of type pglmmObj.

Usage

```
## S3 method for class 'pglmmObj'
fixef(object)
## S3 method for class 'pglmmObj'
ranef(object)
## S3 method for class 'pglmmObj'
sigma(object, ...)
## S3 method for class 'pglmmObj'
coef(object, ...)
## S3 method for class 'pglmmObj'
family(object, ...)
## S3 method for class 'pglmmObj'
nobs(object, ...)
## S3 method for class 'pglmmObj'
ngrps(object, ...)
## S3 method for class 'pglmmObj'
formula(x, fixed.only = FALSE, random.only = FALSE, ...)
## S3 method for class 'pglmmObj'
model.frame(formula, fixed.only = FALSE, ...)
## S3 method for class 'pglmmObj'
model.matrix(object, type = c("fixed", "random"), ...)
## S3 method for class 'pglmmObj'
fitted(object, fixed.only = TRUE, ...)
## S3 method for class 'pglmmObj'

## S3 method for class 'pglmmObj'
plot(x, fixed.only = FALSE, type = NULL, ...)
```

Arguments

object pglmmObj object output from glmm, glmmPen, or glmmPen_FineSearch potentially further arguments passed from other methods . . . an R object of class pglmmObj fixed.only logical value; default TRUE indicates that only the fixed effects should be used in the fitted value/prediction, while FALSE indicates that both the fixed and random effects posterior modes should be used in the fitted value/prediction random.only logical value used in formula; TRUE indicates that only the formula elements relating to the random effects should be returned formula in the case of model.frame, a pglmmObj object type See details of type options for each function under "Functions" section. newdata optional new data.frame containing the same variables used in the model fit procedure

digits

number of significant digits for printing; default of 4

resid_type type of residuals to summarize in output. See predict.pglmm0bj for residual

options available.

Value

The pglmmObj object returns the following items:

fixef vector of fixed effects coefficients

ranef matrix of random effects coefficients for each explanatory variable for each level

of the grouping factor

sigma random effects covariance matrix

scale if family is Gaussian, returns the residual error variance

posterior_samples

Samples from the posterior distribution of the random effects, taken at the end of the model fit (after convergence or after maximum iterations allowed). Can be used for diagnositics purposes. Note: These posterior samples are from a

single chain.

sampling character string for type of sampling used to calculate the posterior samples in

the E-step of the algorithm

results_all matrix of results from all model fits during variable selection (if selection per-

formed). Output for each model includes: penalty parameters for fixed (lambda0) and random (lambda1) effects, BIC-derived quantities and the log-likelihood (note: the arguments BIC_option and logLik_calc in selectControl determine which of these quantities are calculated for each model), the number of non-zero fixed and random effects (includes intercept), number of EM iterations used for model fit, whether or not the model converged (0 for no vs 1 for yes),

and the fixed and random effects coefficients

results_optim results from the 'best' model fit; see results_all for details. BICh, BICh, BICN-

grp, and LogLik computed for this best model if not previously calculated.

family Family

penalty_info list of penalty information

call arguments plugged into glmm, glmmPen, or glmmPen_FineSearch

formula formula

fixed_vars names of fixed effects variables

data list of data used in model fit, including the response y, the fixed effects covariates

matrix X, the random effects model matrix Z (which is composed of values from the standardized fixed effects model matrix), the grouping factor, offset, model frame, and standardization information used to standardize the fixed effects

covariates

optinfo Information about the optimization of the 'best' model

control_info optimization parameters used for the model fit

Estep_init materials that can be used to initialize another E-step (for use in glmmPen_FineSearch)

Gibbs_info list of materials to perform diagnositics on the Metropolis-within-Gibbs sam-

ple chains, including the Gibbs acceptance rates (included for both the independence and adaptive random walk samplers) and the final proposal standard

deviations (included for the adaptive random walk sampler only))

relevant for the output of functions glmm_FA and glmmPen_FA, which are cur-

rently in development and are not yet ready for general use.

showClass("pglmmObj") methods(class = "pglmmObj")

Functions

- fixef.pglmmObj: Provides the fixed effects coefficients
- ranef.pglmm0bj: Provides the random effects posterior modes for each explanatory variable for each level of the grouping factor

• sigma.pglmm0bj: Provides the random effect covariance matrix. If family is Gaussian, also returns the standard deviation of the residual error.

- coef.pglmm0bj: Computes the sum of the fixed effects coefficients and the random effect posterior modes for each explanatory variable for each level of each grouping factor.
- family.pglmmObj: Family of the fitted GLMM
- nobs.pglmm0bj: Number of observations used in the model fit
- ngrps.pglmm0bj: Number of levels in the grouping factor
- formula.pglmm0bj: Formula used for the model fit. Can return the full formula, or just the formula elements relating to the fixed effects (fixed.only = TRUE) or random effects (random.only = TRUE)
- model.frame.pglmmObj: Returns the model frame
- model.matrix.pglmmObj: Returns the model matrix of either the fixed (type = "fixed") or random effects (type = "random")
- fitted.pglmmObj: Fitted values, i.e., the linear predictor of the model.
- predict.pglmm0bj: Predictions for the model corresponding to the pglmmObj output object from the glmmPen package functions. The function predict can predict either the linear predictor of the model or the expected mean of the response, as specified by the type argument. Argument type: character string for type of predictors: "link" (default), which generates the linear predictor, and "response", which generates the expected mean values of the response.
- residuals.pglmmObj: Residuals for the pglmmObj output object from the glmmPen package functions. Argument type: character string for type of residuals to report. Options include "deviance" (default), "pearson", "response", and "working", which specify the deviance residuals, Pearson residuals, the difference between the actual response y and the expected mean response (y mu), and the working residuals (y mu) / mu
- print.pglmmObj: Prints a selection of summary information of fitted model
- summary.pglmmObj: Returns a list of summary statistics of the fitted model.
- logLik.pglmm0bj: Returns the log-likelihood using the Corrected Arithmetic Mean estimator with importance sampling weights developed by Pajor (2017). Degrees of freedom give the sum of the non-zero fixed and random effects coefficients. Citation: Pajor, A. (2017). Estimating the marginal likelihood using the arithmetic mean identity. Bayesian Analysis, 12(1), 261-287.
- BIC.pglmm0bj: Returns BIC, BICh (hybrid BIC developed by Delattre et al., citation: Delattre, M., Lavielle, M., & Poursat, M. A. (2014). A note on BIC in mixed-effects models. Electronic journal of statistics, 8(1), 456-475.), BICNgrps (BIC using N = number of groups in the penalty term), and possibly BIC-ICQ (labeled as "BICq") if the argument BIC_option was set to "BICq" in selectControl (citation for BIC-ICQ: Ibrahim, J. G., Zhu, H., Garcia, R. I., & Guo, R. (2011). Fixed and random effects selection in mixed effects models. Biometrics, 67(2), 495-503.)
- plot.pglmm0bj: Plot residuals for the pglmmObj output object from the glmmPen package. Argument type: character string for type of residuals to report. Options include "deviance" (default for non-Gaussian family), "pearson" (default for Gaussian family), "response", and "working", which specify the deviance residuals, Pearson residuals, the difference between the actual response y and the expected mean response (y mu), and the working residuals (y mu) / mu

plot_mcmc 27

plot_mcmc

Plot Diagnostics for MCMC Posterior Draws of the Random Effects

Description

Provides graphical diagnostics of the random effect posterior draws from the (best) model. Availabile diagnostics include the sample path, histograms, cumulative sums, and autocorrelation.

Usage

```
plot_mcmc(
  object,
  plots = "sample.path",
  grps = "all",
  vars = "all",
  numeric_grp_order = FALSE,
  bin_width = NULL
)
```

Arguments

vars

object an object of class pglmmObj output from either glmmPen or glmmPen_FineSearch.

plots a character string or a vector of character strings specifying which graphical

diagnostics to provide. Options include a sample path plot (default, "sample.path"), autocorrelation plots ("autocorr"), histograms ("histogram"), cumulative sum plots ("cumsum"), and all four possible plot options ("all"). While the "all" option will produce all four possible plots, subsets of the types of plots (e.g. sample path plots and autocorrelation plots only) can be specified with a

vector of the relevant character strings (e.g. c("sample.path", "autocorr"))

grps a character string or a vector of character strings specifying which groups should

have diagnostics provided. The names of the groups match the input group factor

levels. Default is set to 'all' for all groups.

a character string or a vector of character strings specifying which variables

should have diagnostics provided. Default is set to 'all', which picks all variables with non-zero random effects. Tip: can find the names of the random effect variables in the output sigma matrix found in the pglmmObj object, run

sigma(object).

numeric_grp_order

if TRUE, specifies that the groups factor should be converted to numeric values. This option could be used to ensure that the organization of the groups is in the proper numeric order (e.g. groups with levels 1-10 are ordered 1-10, not 1, 10,

2-9).

bin_width optional binwidth argument for geom_histogram from the ggplot2 package.

Default set to NULL, which specifies the default geom_histogram binwidth. This

argument only applies if the "histogram" plot type is selected.

Value

a list of ggplot graphics, each faceted by group and random effect variable. Type of plots specified in the plots argument.

28 rControl

rControl	Control of Latent Factor Model Number Estimation Constructs the control structure for the estimation of the number of latent factors (r) for use within the glmmPen_FA and glmm_FA estimation procedures.

Description

Control of Latent Factor Model Number Estimation

Constructs the control structure for the estimation of the number of latent factors (r) for use within the glmmPen_FA and glmm_FA estimation procedures.

Usage

```
rControl(r = NULL, r_max = NULL, r_est_method = "GR", size = 25)
```

Arguments

r	positive integer specifying number of latent common factors to assume in the model. If NULL (default), this value estimated from the data. See r_est_method for available estimation procedures, and the Details section for further details on the general estimation procedure.
r_max	positive integer specifying maximum number of latent factors to consider. If NULL (default), this value is automatically calculated.
r_est_method	character string indicating method used to estimate number of latent factors r. Default "GR" uses the Growth Ratio method of Ahn and Horenstein (2013). Other available options include "ER" for the Eigenvalue Ratio method of Ahn and Horenstein (2013) and "BN1" or "BN2", the Bai and Ng (2002) method using one of two penalties: (1) $(d+p)/(dp)\log(dp/(d+p))$, (2) $(d+p)/(dp)\log(min(d,p))$ where d is the number of groups in the data and p is the number of total random effect covariates (including the intercept)
size	positive integer specifying the total number of pseudo random effect estimates to use in the estimation procedure for the number of latent factors r, which is restricted to be no less than 25. If this size is greater than the number of groups

in the data (i.e.~the number of levels of the grouping variable), then a sampling procedure is used to increase the number of pseudo estimates to the value of

Details

TODO: additional details on estimation procedure.

size.

select_tune 29

select_tune

Fit a Sequence of Penalized Generalized Mixed Model via Monte Carlo Expectation Conditional Minimization (MCECM) select_tune is used to fit a sequence of penalized generalized mixed models via Monte Carlo Expectation Conditional Minimization (MCECM) for multiple tuning parameter combinations and is called within glmmPen (cannot be called directly by user)

Description

Fit a Sequence of Penalized Generalized Mixed Model via Monte Carlo Expectation Conditional Minimization (MCECM)

select_tune is used to fit a sequence of penalized generalized mixed models via Monte Carlo Expectation Conditional Minimization (MCECM) for multiple tuning parameter combinations and is called within glmmPen (cannot be called directly by user)

Usage

```
select_tune(
 dat,
 offset = NULL,
  family,
  covar = c("unstructured", "independent"),
  group_X = 0:(ncol(dat$X) - 1),
  penalty,
  lambda0_seq,
  lambda1_seq,
  alpha = 1,
  gamma_penalty = switch(penalty[1], SCAD = 4, 3),
  trace = 0,
  u_init = NULL,
  coef_old = NULL,
  adapt_RW_options = adaptControl(),
 optim_options = optimControl(),
 BIC_option = c("BICq", "BICh", "BIC", "BICNgrp"),
 BICq_calc = TRUE,
  logLik_calc = switch(BIC_option[1], BICq = FALSE, TRUE),
 BICq_posterior = NULL,
  checks_complete = FALSE,
 pre_screen = TRUE,
  ranef_keep = NULL,
  lambda.min.full,
  stage1 = FALSE,
  progress = TRUE
)
```

Arguments

dat

a list object specifying y (response vector), X (model matrix of all covariates), Z (model matrix for the random effects), and group (numeric factor vector whose

30 select_tune

value indicates the study, batch, or other group identity to which on observation belongs)

offset

This can be used to specify an *a priori* known component to be included in the linear predictor during fitting. Default set to NULL (no offset). If the data argument is not NULL, this should be a numeric vector of length equal to the number of cases (the length of the response vector). If the data argument specifies a data.frame, the offset argument should specify the name of a column in the data.frame.

family

a description of the error distribution and link function to be used in the model. Currently, the glmmPen algorithm allows the Binomial, Gaussian, and Poisson families with canonical links only.

covar

character string specifying whether the covariance matrix should be unstructured ("unstructured") or diagonal with no covariances between variables ("independent"). Default is set to NULL. If covar is set to NULL and the number of random effects predictors (not including the intercept) is greater than or equal to 10 (i.e. high dimensional), then the algorithm automatically assumes an independent covariance structure and covar is set to "independent". Otherwise if covar is set to NULL and the number of random effects predictors is less than 10, then the algorithm automatically assumes an unstructured covariance structure and covar is set to "unstructured".

group_X

vector describing the grouping of the covariates in the model matrix.

penalty

character describing the type of penalty to use in the variable selection procedure. Options include 'MCP', 'SCAD', and 'lasso'. Default is MCP penalty. If the random effect covariance matrix is "unstructured", then a group MCP, group SCAD, or group LASSO penalty is used on the random effects coefficients. See Breheny and Huang (2011) <doi:10.1214/10-AOAS388> and Breheny and Huang (2015) <doi:10.1007/s11222-013-9424-2> for details of these penalties.

lambda0_seq

a sequence of non-negative numeric penalty parameters for the fixed and random effect coefficients (lambda0_seq and lambda1_seq, respectively). If NULL, then a sequence will be automatically calculated. See 'Details' section for more details on these default calculations.

lambda1_seq

a sequence of non-negative numeric penalty parameters for the fixed and random effect coefficients (lambda0_seq and lambda1_seq, respectively). If NULL, then a sequence will be automatically calculated. See 'Details' section for more details on these default calculations.

alpha

Tuning parameter for the Mnet estimator which controls the relative contributions from the MCP/SCAD/LASSO penalty and the ridge, or L2, penalty. alpha=1 is equivalent to the MCP/SCAD/LASSO penalty, while alpha=0 is equivalent to ridge regression. However, alpha=0 is not supported; alpha may be arbitrarily small, but not exactly zero

gamma_penalty

The scaling factor of the MCP and SCAD penalties. Not used by LASSO penalty. Default is 4.0 for SCAD and 3.0 for MCP. See Breheny and Huang (2011) <doi:10.1214/10-AOAS388> and Breheny and Huang (2015) <doi:10.1007/s11222-013-9424-2> for further details.

trace

an integer specifying print output to include as function runs. Default value is 0. See Details for more information about output provided when trace = 0, 1, or 2.

u_init

matrix giving values to initialize samples from the posterior. If Binomial or Poisson families, only need a single row to initialize samples from the posterior; if Gaussian family, multiple rows needed to initialize the estimate of the residual

select_tune 31

error (needed for the E-step). Columns correspond to the columns of the Z random effect model matrix.

coef_old v
adapt_RW_options

vector giving values to initialized the coefficients (both fixed and random effects)

a list of class "adaptControl" from function adaptControl containing the control parameters for the adaptive random walk Metropolis-within-Gibbs procedure. Ignored if optimControl parameter sampler is set to "stan" (default) or "independence".

optim_options

a structure of class "optimControl" created from function optimControl that specifies several optimization parameters. See the documentation for optimControl for more details on defaults.

BIC_option

character string specifying the selection criteria used to select the 'best' model. Default "BICq" option specifies the BIC-ICQ criterion (Ibrahim et al (2011) <doi:10.1111/j.1541-0420.2010.01463.x>), which requires a fit of a 'minimum penalty' model; a small penalty (the minimum of the penalty sequence) is used for the fixed and random effects. See "Details" section for what these small penalties will be. The "BICh" option utilizes the hybrid BIC value described in Delattre, Lavielle, and Poursat (2014) <doi:10.1214/14-EJS890>. The regular "BIC" option penalty term uses (total non-zero coefficients)*(length(y) = total number observations). The "BICNgrp" option penalty term uses (total non-zero coefficients)*(nlevels(group) = number groups).

BICq_calc

logical value indicating if the BIC-ICQ criterion should be used to select the best model.

logLik_calc

logical value specifying if the log likelihood (and log-likelihood based calculations BIC, BICh, and BICNgrp) should be calculated for all of the models in the selection procedure. If BIC-ICQ is used for selection, the log-likelihood is not needed for each model. However, if users are interested in comparing the best models from BIC-ICQ and other BIC-type selection criteria, setting logLik_calc to TRUE will calculate these other quantities for all of the models.

BICq_posterior

an optional character string expressing the path and file basename of a file combination that will file-back or currently file-backs a big.matrix of the posterior samples from the minimal penalty model used for the BIC-ICQ calculation used for model selection. T (BIC-ICQ reference: Ibrahim et al (2011) <doi:10.1111/j.1541-0420.2010.01463.x>). If this argument is specified as NULL (default) and BIC-ICQ calculations are requested (see selectControl) for details), the posterior samples will be saved in the file combination 'BICq_Posterior_Draws.bin' and 'BICq_Posterior_Draws.desc' in the working directory. See 'Details' sec-

file-backed big matrix.

checks_complete

logical value indicating if several data checks have been completed.

pre_screen

logical value indicating whether pre-screening should be performed before model selection (default TRUE). If the number of random effects covariates considered is 4 or less, then no pre-screening will be performed. Pre-screening removes random effects from consideration during the model selection process, which can significantly speed up the algorithm. See "Details" section for a further discussion.

tion for additional details about the required format of BICq_posterior and the

ranef_keep

vector of 0s and 1s indicating which random effects should be considered as non-zero at the start of the algorithm. For each random effect, 1 indicates the random effect should be considered non-zero at start of algorithm, 0 indicates otherwise. The first element for the random intercept should always be 1.

32 sim.data

lambda.min.full

a vector of two numeric values that gives the fixed and random effect penalty values to use in pre-screening and/or the minimal penalty model fit for the BIC-

ICQ calculation (if applicable)

stage1 logical value indicating if the first stage of the abbreviated two-stage grid search

in the model selection procedure is being performed. FALSE if either performing the second stage of the abbreviated two-stage grid search or if performing the

full grid search over all possible penalty parameter combinations.

progress a logical value indicating if additional output should be given showing the progress

of the fit procedure. If TRUE, such output includes iteration-level information for the fit procedure (iteration number EM_iter, number of MCMC samples nMC, average Euclidean distance between current coefficients and coefficients from t-defined in <code>optimControl</code>—iterations back EM_conv, and number of non-zero fixed and random effects covariates not including the intercept). Additionally, <code>progress = TRUE</code> gives some other information regarding the progress of the variable selection procedure, including the model selection criteria and log-

likelihood estimates for each model fit. Default is TRUE.

Value

A list with the following elements:

results matrix of summary results for each lambda tuning parameter combination, used

to select the 'best' model

out list of fit_dat results for the best model

coef matrix of coefficient results for each lambda tuning parameter combination.

Rows correspond with the rows of the results matrix.

sim.data Simulates data to use for the glmmPen package Simulates data to use

for testing the glmmPen package. Possible parameters to specify includes number of total covariates, number of non-zero fixed and random effects, and the magnitude of the random effect covariance values.

Description

Simulates data to use for the glmmPen package

Simulates data to use for testing the glmmPen package. Possible parameters to specify includes number of total covariates, number of non-zero fixed and random effects, and the magnitude of the random effect covariance values.

Usage

```
sim.data(
    n,
    ptot,
    pnonzero,
    nstudies,
    sd_raneff = 1,
    family = "binomial",
```

sim.data 33

```
corr = NULL,
seed,
imbalance = 0,
beta = NULL,
pnonzerovar = 0
)
```

Arguments

n integer specifying total number of samples to generate

ptot integer specifying total number of covariates to generate (values randomly gen-

erated from the standard normal distribution)

pnonzero integer specifying how may of the covariates should have non-zero fixed and

random effects

nstudies number of studies/groups to have in the data

sd_raneff non-negative value specifying the standard deviation of the random effects co-

variance matrix (applied to the non-zero random effects)

family character string specifying which family to generate data from. Family options

include "binomial" (default), "poisson", and "gaussian".

corr optional value to specify correlation in the random effects covariance matrix.

Default NULL

seed integer to use for the setting of a random seed

imbalance integer of 0 or 1 indicating whether the observations should be equally dis-

tributed among the groups (0) or unequally distributed (1).

beta numeric vector of the fixed effects (including intercept)

pnonzerovar non-negative integer specifying the number of covariates with a zero-valued

fixed effect but a non-zero random effect.

Value

list containing the following elements:

y vector of the response

X model matrix for the fixed effects

Z model matrix for the random effects, organized first by variable and then by

group

pnonzero number of non-zero fixed effects

z1 values of the random effects for each variable for each level of the grouping

factor

group grouping factor

X0 model matrix for just the non-zero fixed effects
